

Lab-4 Ex5 - Count the Votes!

In a committee, there are 10 members, in which they are going to decide which of the 3 candidates to be the committee chairman. The candidates are labeled as 1, 2, and 3. Each member can either vote 1, 2 or 3 (assuming no invalid vote).

Write a program to decide who is the chairman. It is possible that some candidates have the same number of votes, such that the chairman cannot be decided in this vote.

You will also find that it is very similar to one of the examples we have in this Week's lecture.

Please follow the following **pseudocode** to complete the program:

Declare an array `countVote[3]` to count the votes, remember to initialize the array

Read the number, and count the vote.

Do (copy and paste) statements in the previous step for 9 more times

Determine the largest vote

See if more than one candidate shares the same largest vote

Output the results

User-input integers are ***bold and italic*** in the following sample runs.

Sample run #1:

1 2 2 3 2 3 1 2 2 1

Congratulations! Candidate 2 is the next committee chairman.

Sample run #2:

1 2 3 1 2 3 1 2 1 2

We cannot decide our committee chairman in this vote.
