

Lab-2 Ex3 - Splitting the Bill (PreLab*)

This is a PreLab exercise. Please do the PreLabs after lecture and before you come to lab!

Luncheon of the Boating Party (1881). Wikipedia

When you go to the restaurants, it is very common to split the bills. Let's make a very simple bill splitting program in C.

The program will ask for:

1. How many ***people*** enjoyed the meal
2. The total ***cost*** of the meal
3. The ***tips***

Assume everyone will share both the cost of the meal and the tips. The program should output ***how much each person should pay***, in 2 decimal places.

Are you aware of the data type of the above three input items? In C, it is very important to get the data types correct. In this case, it's clear enough, with common sense:

1. How many people enjoyed the meal - **integer**
2. The total cost of the meal - **floating point number**
3. The tips - **floating point number**

Assuming all input are valid, here is how the program should run:

Sample Run (user input is bolded and in italic)

Input number of people: ***3***

Input cost of meal: ***95.5***

Input tips: ***2.5***

Everyone pays: 32.67
