

Lab-2 Ex5 - Reciprocal

Are you aware that you can print the values of multiple variables out, with a single statement of `printf()`? For instance, the following statement:

```
printf("My date of birth is %d-%d-%d\n", 28, 2, 2000);
```

will give an output of:

```
My date of birth is 28-2-2000
```

Let's create a simple C program to get an integer `x` from user and calculate its reciprocal ($1/x$). For instance, when user input a **positive integer**, like this:

3

You will give me the output, in **4 decimal places**:

```
1 / 3 = 0.3333
```

It's very simple right? Nothing will go wrong! **wink**

Here are a few sample runs, please make sure that your program follows the exact behavior.

Sample Run #1 (user input is bolded and in italic)

1

```
1 / 1 = 1.0000
```

Sample run #2 (user input is bolded and in italic)

7

```
1 / 7 = 0.1429
```

Sample run #3 (user input is bolded and in italic)

10

```
1 / 10 = 0.1000
```
