

Lab-7 Ex4 - Prime Numbers, Again!

(Prelab*)

In this exercise, please write a program that requests for two positive integers a and b within the range of 2 to 10000 from the user, and then print **ALL** the prime numbers within the range of b to a **inclusively** in descending order. If there are no prime numbers between them, output nothing.

You may assume that the user input is always valid and a is always less than or equal to b .

Remember a number is prime if it is not divisible by any positive integers less than itself except 1. You may find your previous exercises helpful, but mind the hidden bugs in your work!

User-input numbers are ***bold and italic*** in the following sample runs. Note that in general there is a space following each number output.

Sample run #1:

Input a and b: ***2 20***

19 17 13 11 7 5 3 2

Sample run #2:

Input a and b: ***9400 9410***

9403

Sample run #3:

Input a and b: ***53 53***

53

Sample run #4:

Input a and b: ***98 100***

(Note: No prime numbers in range, thus no numbers are printed)
